We report the experimental demonstration of waveguides built around layer-by-layer photonic crystals. An air gap introduced between two photonic crystal walls was used as the waveguide. We observed full (100%) transmission of the electromagnetic (EM) waves through these planar waveguide structures within the frequency range of the photonic band gap. The dispersion relations obtained from the experiment were in good agreement with the predictions of our waveguide model.

We constructed the parallel-plate type waveguide by using two separate three unit cell thick layer-by-layer photonic crystals. The crystals were brought together along the stacking direction with a separation width \( d \) between them, while keeping a mirror type of symmetry between the rods of the two crystals (see Fig. 1). This is very similar to a Fabry–Perot type cavity, where the two crystals act as the mirrors of the resonator. In a Fabry–Perot type cavity, the propagation direction of the EM wave is perpendicular to the plane of the cavity. If the propagation direction is chosen to be parallel to the plane of the cavity, the structure will have the geometry of a parallel-plate waveguide. We expect the wave to be guided through the introduced air gap, starting from a cutoff frequency which depends on the width of the gap. The guiding is limited with the full band gap frequency range of the

In our experiments, we used a layer-by-layer dielectric photonic crystal based on square shaped alumina rods, with center to center separation of 1.12 cm. The crystal exhibits a three dimensional photonic band gap with a mid-gap frequency around 12 GHz.14 Figure 1 shows the schematics of the measurement setup that was used in our experiments. We used an HP 8510C network analyzer and microwave horn antennas to measure the transmission-phase and transmission-amplitude properties of the two different waveguide structures investigated in this letter: a parallel-plate waveguide and an L-shaped waveguide.

The basic motivation in photonic crystal based waveguides arose when the following properties of these crystals, which are essential for many applications, were considered.5 First, photonic crystals have the property of reflecting the EM waves within the band gap frequencies in all directions. Second, defect structures in which the EM wave is trapped, can be created by breaking the periodicity of the crystal. Combining these two properties, an opening carved all through an otherwise-perfect crystal (which resembles a continuous defect structure), may serve as a waveguide.5 Once the EM wave is coupled inside the guide, the trapped wave, which has no where else to go, is guided through the opening inside the crystal. This guiding mechanism is superior to traditional waveguides which rely on total internal reflection of the EM waves.6 The serious leakage problem for the EM waves traveling around tight corners in a traditional waveguide can be solved by using a photonic crystal based waveguide, and smaller scale optoelectronic integrated circuits can be successfully built.23

**FIG. 1.** Experimental setup used to investigate the parallel-plate (upper case) and L-shaped (lower case) waveguide structures.
FIG. 2. Transmission amplitude measured from parallel-plate waveguides as the separation width of the waveguide is changed. The numbers given in the plot are assigned to width of the guides as (1) 18, (2) 16, (3) 14, (4) 12, (5) 10.5 mm.

photonic crystal, for which the crystal has the property of reflecting the EM waves in all directions.

We tested this waveguiding argument, by measuring the transmission properties of these structures along the plane of the cavity. Figure 2 shows the transmission properties of the waveguide structure for different separation widths. We observed full transmission (100%) of the EM waves along a certain frequency range. The waveguiding was first observed at a minimum separation width around 10 mm, and the cutoff shifted to lower frequency values as the width of the air gap was increased. Independent of the width of the cavity, the guiding was observed to vanish at a fixed upper cutoff frequency (13.2 GHz), which corresponds to the upper band edge of the photonic band gap. This is along our expectations as the crystals do not act as mirrors (in all directions) beyond the full band gap frequencies. The lower cutoff frequency is determined by the width of the cavity and corresponds to the resonant frequency of the Fabry–Perot resonator. This resonant frequency can easily be predicted by a Fabry–Perot defect model we have used in our earlier work.24

We investigated the dispersion characteristics of the waveguide by measuring the phase difference of the transmitted wave introduced by the guide. This phase difference, \( \phi_{\text{trans}} \), can be written as \( \phi_{\text{trans}} = kL - k_zL \), where \( k = (2\pi/c)f \) is the free space wavevector, \( k_z \) is the component of the wave vector along the waveguide [see Fig. 3(a)], and \( L \) is the length of the waveguide. This can be used to find the normalized propagation constant, \( k_z/k \), as a function of frequency.

\[
\frac{k_z}{k} = 1 - \frac{\phi_{\text{trans}}}{kx} = 1 - \frac{\phi_{\text{trans}}}{2\pi f}. \tag{1}
\]

The dispersion relation calculated by this phase-measurement method is shown in Fig. 3(b) (thick solid lines) for different separation widths of the waveguide. The separation widths are chosen to be the same with those widths used in the transmission measurements.

The dispersion relations can also be calculated by a parallel-plate waveguide model. Since the dielectric photonic crystal walls of the waveguide has a certain penetration depth that can be calculated using the reflection-phase information from the walls of the cavity, we can define an effective width for the waveguide. This approach was previously used to investigate the defect characteristics built around dielectric and metallic photonic crystals.24 In the calculation of this effective penetration depth, one has to consider the angle dependence of the reflection phase, since the wave is considered to be bouncing between the walls of the waveguide at different angles for different frequencies. We measured the reflection phase of the EM waves from the walls of the cavity for the frequency range of the band gap, as a function of angle \( \theta \), where \( \theta \) is taken to be the angle between the wavevector \( k \) and its component along the stacking direction of the crystal \( k_z \) as shown in Fig. 3(a). We calculated the effective width of the waveguide using the total phase contributions of both walls of the cavity, \( \phi_{\text{ref}}(\theta,f) \).

\[
d_{\text{eff}} = d + \frac{\phi_{\text{ref}}(\theta,f)}{2k}. \tag{2}
\]

where \( d \) is the actual separation width of the waveguide. The corresponding propagation angle for each frequency is obtained from Eq. (1) as,

\[
\theta = \arcsin \left( \frac{k_z}{k} \right) = \arcsin \left( 1 - \frac{\phi_{\text{trans}}c}{2\pi f} \right). \tag{3}
\]

This angle information can be used in Eq. (2) to find an effective width of the guide at each frequency. The \( k_z \) component of the wave vector can be calculated as \( k_z = 2\pi/\lambda_c \), where \( \lambda_c = 2d_{\text{eff}} \) is the cutoff wavelength of the waveguide. The dispersion relation can now be expressed as

\[
\frac{k_z}{k} = \sqrt{\frac{k^2 - k_c^2}{k}}. \tag{4}
\]

Note that, since \( k_c \) is considered to be constant, after some frequency, the square root becomes real, so that the waves after that cutoff frequency (defined by \( k_c \)) can propagate in
the wave through sharper bends. To demonstrate this effect, waveguides were predicted to have the property of guiding the second configuration of the setup, the photonic crystal making 90° with the first one, as shown in a parallel-plate waveguide structure, to the input of another but identical waveguide. We coupled the output of the previously described transmitter antennas, and measuring the transmission properties of the waveguide. As can be seen from the plots, the guide is slightly asymmetric. We checked the effect of this asymmetry by interchanging the positions of the receiver and transmitter antennas, and measuring the transmission properties of the waveguide. The resulting transmission characteristics of the waveguide were very similar to the original measurements. The relatively poor performance of the transmission magnitude can be further increased by a proper design of the bend. These results show that photonic crystals can be used for various waveguide configurations.

In summary, we have experimentally verified that EM wave can be guided with 100% transmission, using three dimensional photonic crystals. We have developed a parallel-plate waveguide model for our structures. The dispersion diagrams calculated using the transmitted phase measurements and by the waveguide model were in good agreement. We also observed 35% transmission for the EM waves traveling through a sharp bend in an L-shaped waveguide.
